OIL SEALS & O-RINGS

**KOYO SEIKO CO., LTD.
KOYO SEALING TECHNO CO., LTD.**

Preface

This catalog lists Koyo oil seals and O-rings, including all items of the dimension series specified in ISO, JIS and JASO (Japanese Automobile Standards Organization) standards. This catalog is also based on knowledge gained from our supply record, experience, expertise, technologies, and research developments that Koyo has acquired in cooperation with customers since its foundation in 1964.

A specialty of this new catalog is the comprehensive information, it offers regarding the selection and handling of oil seals and O-rings.

Energy-saving, environment-friendly considerations are in great demand, and Koyo makes efforts to continue further research and development in response to these.

We hope that this catalog will be helpful for you to get another new idea from Koyo products.

- If you have any questions or requests in selecting oil seals, please fill out the Request Forms for Oil Seal Design and Production provided at the end of this catalog and send them by fax to your nearest Koyo operation.

★ The contents of this catalog are subject to change without prior notice. Every possible effort has been made to ensure that the data listed in this catalog is correct. However, we can not assume responsibility for any errors or omissions.

Reproduction of this catalog without written consent is strictly prohibited.

Koyo Oil Seals: Features

1. Lightweight, compact, and energy-saving

Koyo oil seals offer high sealing performance, while being compact with reduced seal width. They help reduction of machine weight, size, and energy consumption.

2. High sealing performance by optimum lip design

Koyo oil seals employ a linear-contact lip, which provides proper radial lip load. The lip design ensures excellent sealing performance, low torque, proper flexibility and high allowability for eccentricity.

3. Low heat generation and long service life by highly self-lubricating rubber materials

Based on extensive research and experimentation, Koyo has succeeded in developing seal rubber materials with high self-lubrication performance. These rubber materials show limited chemical changes such as hardening, softening and/or aging.

These materials can offer long service life under high temperature and high speed rotation because of curbed heat generation.

4. High sealing performance and long service life by hydrodynamic ribs (Perfect Seal, Helix Seal, Super Helix Seal)

The sealing lip has special spiral threads (hydrodynamic ribs) in one or two directions, which drastically improved sealing performance and service life.

Various oil seals

Large-size oil seals

■ Koyo O-Rings: Features

1. High sealing performance and reliability

High sealing performance against water, oil, air, various gases and chemicals.

2. Available in a full lineup of designs and sizes

3. Easy handling

■ Various O-rings

Koyo Functional Products: Features

Koyo produces various functional products based on advanced sealing technologies and sophisticated manufacturing expertise acquired through extensive research and production.

Koyo functional products are very effective in improv-

ing machine performance, reducing weight, size, noise and vibration.

Consult Koyo if there is no product in this catalog that exactly matches your requirements--Koyo can custom-design products.

1. Functional products for automobiles and forklift trucks

■ Various functional products

- Center bearing units
- Bearings molded with vibration isolating rubber
- Spark-plug tube gaskets
- Plastic gear shafts
- Pulley units

■ Bonded piston seals for automatic transmissions

■ Friction dampers for manual transmissions

■ Various boots for joints

2. Functional products for motorcycles

■ Various functional products

- Air cleaner joints
- Carburetor joints
- Sprocket wheels
- Muffler joints
- Plastic gear shafts
- Oil strainers
- Mesh gaskets
- Ball-component clutch releases
- Vertical gaskets

FEM (Finite Element Method) Analysis

Koyo uses the non-linear finite element method to analyze non-linear materials such as rubber, for which accurate analysis was difficult before. The company has been studying sealing-mechanism theories by this method in order to develop new products.

The findings so far have been very useful for basic research as well as for rubber-component design. The FEM is our common design tool today, enabling highly reliable analysis and evaluation, speeding up research and product development.

1.1 Nomenclature and functions of seal components

(1) Nomenclature of components

Oil seals work to prevent leakage of lubricants such as oil and operational media from inside and also to prevent the entry of dust and contaminants from outside.

Oil seals are designed in a variety of shapes according to the applications and substances to be sealed.

Fig. 1.1.1 shows a typical shape of seal and its component nomenclature.

Fig. 1.1.1 Typically shaped oil seal and component nomenclature

(2) Component functions

① Main lip

The main lip is the most critical component of seals. Its sealing edge contacts closely around the shaft surface in order to provide excellent sealing performance.

During service, seals are placed under various stresses, such as machine vibration, shaft runout, and changes in the temperature and pressure of substances to be sealed.

The main lip is designed so as to generate force (radial lip load) and to keep the sealing edge consistently in close contact with the shaft under such stresses.

For such stresses, seal rubber material is made from synthetic rubber, which is highly elastic and abrasion-resistant.

② Minor lip

The minor lip prevents the entry of dust and contaminants from outside. As a prelubricant, grease can be retained in the space between main lip and minor lip.

③ Sealing edge

The sealing edge is wedge-shaped and contacts directly in linear with the shaft to ensure sufficient sealing performance and to stand against temperature change and high speed rotation.

④ Spring

The spring supplements the radial lip load at the sealing edge to ensure tight contact between sealing edge and shaft and enhanced sealing performance. The spring also hinders the deterioration of main lip sealing performance caused by high heat or others.

Because this spring is a closely wound type coil, the initial tension can be obtained high level, and then changes in load characteristics can be gradual with respect to spring elongation. Radial lip load at the sealing edge can thus be kept stable at an appropriate level.

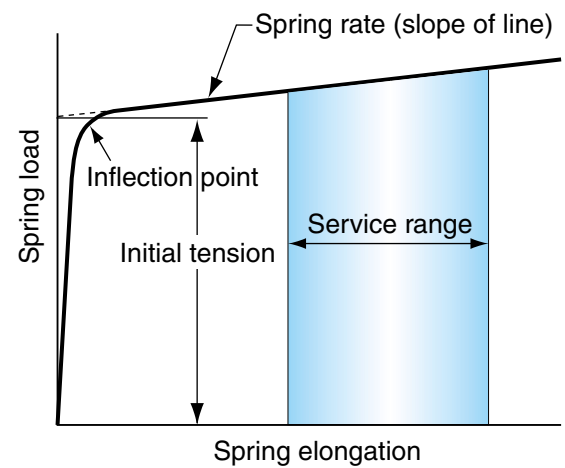

Fig. 1.1.2 Spring properties for seal

⑤ Metal case

The metal case provides rigidity on seal, helping it settle on the housing securely. It also ensures easy seal handling and mounting.

⑥ O.D surface

Seals are fitted tightly into the housing bore generally. O.D surface prevents the oil leakage through fitting area, while excluding contaminants. This surface may be made of either metal or rubber, depending on the application.

⑦ Nose

The front end face of the seal is called the nose. Seals are usually mounted for the nose to face the substances to be sealed. The nose is made of rubber and forms a gasket seal when compressed on housing shoulder.

⑧ Back face

The side face of the air side is called the back face. It is usually mounted so as not to contact the substances to be sealed.

1.2 Seal numbering system

Table 1.2.1 Seal numbering system

| | |
|---|---|
| Example | |
| MH S A 45 68 9 J | |
| Special shape code J: | Additional code is added here as an identifier when two or more seals have exactly the same type codes and dimensional numbers. |
| Dimensional numbers | Shaft number 45: The seal suits the shaft diameter of 45 mm. Housing bore number ... 68: The seal suits the housing bore diameter of 68 mm. Width number 9: The seal width is 9 mm. |
| Lip type code | No code: without minor lip A: with minor lip |
| Spring code | No code: without spring S: with spring |
| Seal type code | MH: O.D wall is rubber material HM: O.D wall is metal case HM(S)H: O.D wall is metal with a reinforcing inner metal case. (A spring is always provided for this type.) |
| Remark) For the type codes of special type seals, refer to Section 1.3. | |

Koyo oil seals: Features

1.3 Seal types

(1) Common seal types and their features

Seals are classified by O.D wall material, lip type and whether with spring or without spring. Major oil seals are specified in ISO 6194, JIS B 2402, and JASO F 401. Table 1.3.1 shows common seal types.

Table 1.3.2 lists the seal type codes used at Koyo, along with the corresponding codes used in the ISO, JIS, and JASO standards.

Table 1.3.1 Oil seals of common types

| | With spring ¹⁾ | | | Without spring | |
|-------------------------------------|---|------------------------------|---|--|------------------------------|
| | Rubber O.D wall ²⁾ | Metal O.D wall ³⁾ | Metal O.D wall (with a reinforcing inner metal case) ^{3) 4)} | Rubber O.D wall ²⁾ | Metal O.D wall ³⁾ |
| Without minor lip | | | | | |
| Type code | MHS | HMS | HMSH | MH | HM |
| With minor lip ⁵⁾ | | | | | |
| Type code | MHSA | HMSA | HMSAH | MHA | HMA |
| Features of each type | 1) With spring type secures stable sealing performance 2) Rubber O.D wall type provides stable sealing performance around the seal O.D surface 3) Metal O.D wall type ensures improved fitting retention between the seal O.D and | | | the housing bore 4) Reinforcing inner metal case in the metal O.D wall type protects the main lip 5) With minor lip type is applied for the application where there are many contaminants at the air side (back face side) | |

Table 1.3.2 Koyo oil seal type codes corresponding to the codes used in Industrial standards

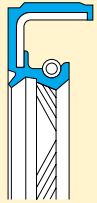

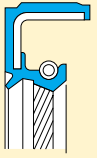

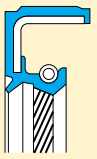

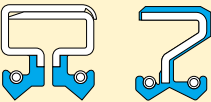

| KOYO | ISO | JIS | JASO |

| HMA | — | — | PM |

(2) Special seal types and their features

Koyo provides special seals to meet a wide variety of machines and applications:

Table 1.3.3 Oil seals of special types (1)

⊙: For bi-directional rotation ○: For uni-directional rotation

| Seal type | Type code and shape | Motion | Features | Applications |
|--------------------------|---|--------|---|--|
| Perfect Seals |  MHSA...XBT | ⊙ | The hydrodynamic ribs provided in two directions on the lip ensure improved pumping effect and higher sealing performance in both rotational directions | Reduction gears input shafts Differential gear sides |
| Helix Seals |  MHSA...XRT MHSA...XLT | ○ | Hydrodynamic ribs are effective for uni-directional rotation enhancing pumping effect | Engine crankshafts Oil pumps Differential gear sides Reduction gears input shafts |
| Super Helix Seals |  MHSA...XRT MHSA...XLT | ○ | Optimized hydrodynamic ribs ensure high pumping effect for long time | Engine crankshafts Oil pumps Differential gear sides Reduction gears input shafts |
| Double Lip Seals |  HMSD MHSD | ⊙ | These seals can separate and seal two kinds of oil or fluid on one shaft | Engaged positions of transfer system |

■ Perfect Seal

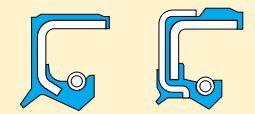

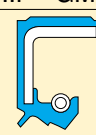

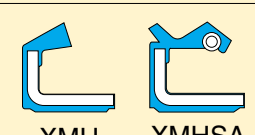

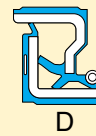

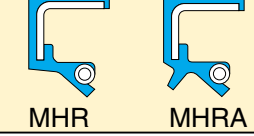

■ Helix Seal

■ Super Helix Seal

Table 1.3.3 Oil seals of special types (2)

⊙: For bi-directional rotation –: For reciprocation

| Seal type | Type code and shape | Motion | Features | Applications |
|---|--|--------|--|--|
| Pressure-resistant Seals |  MHP...P GMHP...P | ⊙ | These seals are designed to reduce lip deformation caused by oil pressure. Sealing performance does not being deteriorated under high pressure | Hydraulic motors Motorcycle engine crankshafts Power steering rods |
| Reciprocating Seals |  MHR...R | ⊙ – | These seals are designed to accommodate shaft strokes and to lessen lip deformation caused by shaft reciprocating motion | Power steering rods CVT shafts of motorcycles |
| External Lip Seals |  XM XMHP | ⊙ | This type of seal has the lip on its outside, sealing the contact with housing | Applications of housing rotation |
| Seals with Side Lip |  MHP...S | ⊙ | A large side lip ensures prevention of entry of dust/water | Differential gear sides |
| Mud-resistant Seals with Integrated Sleeve |  D | ⊙ | These seals are designed to enhance prevention of entry of mud | Wheel hubs |
| HR Seals |  HRSA | ⊙ | HR seals ensures sealing performance around seal O.D and retain fitting with housing | Engine crankshafts Wheel hubs |
| SIM Seals |  MHR MHP | ⊙ | The seals are spring-in mold type, which protect the spring from dust and enhance durability | Plug tubes Wheel hubs |

■ Seal with Side Lip

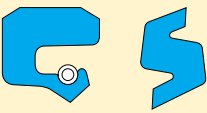

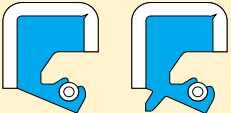

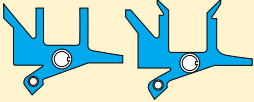

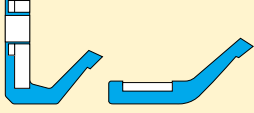

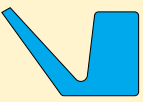

■ HR Seal

■ SIM Seal

Table 1.3.3 Oil seals of special types (3)

⊙: For bi-directional rotation

| Seal type | Type code and shape | Motion | Features | Applications |
|--------------------------|---|--------|--|---|
| Full Rubber Seals |  MS MZ | ⊙ | Mounting is easy because of full rubber construction. Split type seals are available which can be mounted directly, not necessarily mounting from the shaft end | Plummer blocks Long shafts, complex shaped shaft |
| YS Type Seal |  YS YSA | ⊙ | Wide range sizes for medium and large shafts are available | Various medium and large size machines Rolling mills |
| MORGOIL Seals |  MS...J MS...NJ | ⊙ | MORGOIL seals are used exclusively on MORGOIL bearings | MORGOIL bearings |
| Water Seals |  XMHE | ⊙ | The double lips ensure improved water-proof performance | Rolling mill roll necks |
| Scale Seals |  WR WR...BJ | ⊙ | These seals prevent the ingress of scales in rolling oil | Rolling mill roll necks |
| V-Rings |  MV...A | ⊙ | With these rings, shafts can be sealed at the end. The V-rings can be mounted easily in limited spaces | Rolling mill roll necks |

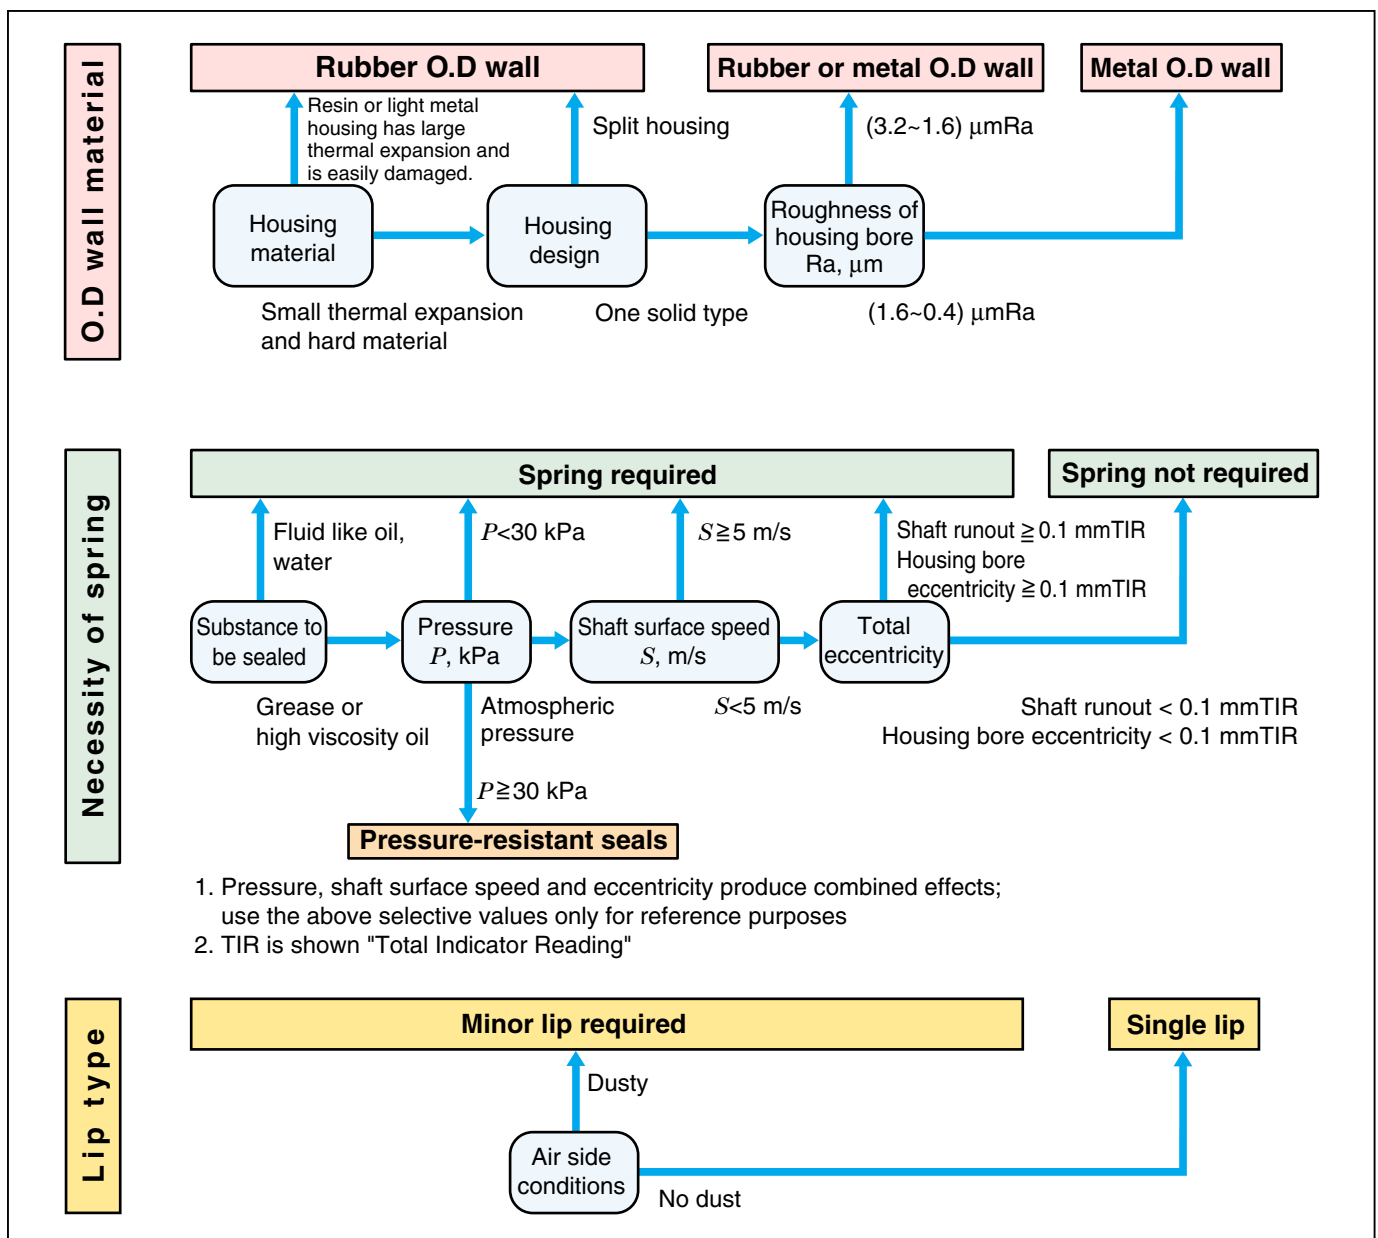

1.4 Selection of seal

(1) Selection of seal type

To select a seal type, seal O.D wall material, lip type, and whether a spring should be provided or not should be decided based on operational conditions as shown in flowcharts below.

If you need oil seals used under special conditions not covered in the flowcharts, refer to Section 1.3 Paragraph (2), "Special seal types and their features."

Table 1.4.1 Flowcharts for oil seal selection

★Seal selection example

- Housing: Made of steel, one solid design, bore surface roughness 1.8 μmRa
- Substance to be sealed: Grease
- Pressure: Atmospheric
- Shaft surface speed: 6 m/s
- Air side condition: Dusty

According to the above flowcharts, a seal with a rubber or metal O.D wall, spring, and minor lip is the most suitable for these conditions. The MHSA or HMSA seal is recommended in this case.

(2) Selection of rubber material

Rubber materials should be selected according to temperature conditions and substances to be sealed.

Table 1.4.2 lists rubber materials along with their operational temperature ranges and chemical resistance characteristics.

- ⊙: The rubber has excellent resistance to the substance to be sealed
- : The rubber has good resistance to the substance except under extreme conditions
- △: The rubber is not resistant to the substance except under specific favorable conditions
- ×: The rubber is not resistant to the substance

Table 1.4.2 Rubber materials, operational temperature ranges and chemical resistance characteristics

| Rubber material (ASTM code) | Grade (ref. number) | Features | Operational temperature range ¹⁾²⁾ Lower limit Upper limit Normal operation range -50 0 50 100 150 200 °C | Fuel oil | | | Lubrication oil and hydraulic fluid | | | | | | Grease | | | Chemicals and water | | | | | | | | | | |
|------------------------------------|--|---|---|--------------------|--------------------|---------------------|-------------------------------------|-------------|------------|------------------------------|-------------|----------------|------------------|-----------|--------------|---------------------|------------|---------------|---------|-------|--------|-------|-------------------------------------|--------------------------------|-------------------------------|--------------------------|

| Hydrogenated nitrile rubber (HNBR) | Standard type (500) | Compared with nitrile rubber, superior in resistance to heat and to abrasion | -30 140 | ○ | ○ | ⊙ | ⊙ | ⊙ | ⊙ | ⊙ | ⊙ | ○ | × | × | ⊙ | ⊙ | △ | ⊙ | ○ | △ | × | ⊙ | △ | ○ | ○ | ○ |
| Acrylic rubber (ACM) | Standard type (234) | High resistant to oil and to abrasion | -20 150 | | | | | | | | | | | | | | | | | | | | | | | |
| | High- and low-temperature resistant type (240) | Improved low-temperature resistance. Low strain and same level heat resistance as standard type | -30 150 | ○ | △ | ⊙ | ⊙ | ⊙ | ⊙ | ⊙ | ⊙ | × | × | × | ⊙ | ⊙ | × | ⊙ | × | × | × | × | × | × | △ | × |
| Silicone rubber (VMQ) | Standard type (306) | Wide operational temperature range and good abrasion resistance | -50 170 | × | × | ○ | × | ○ | ○ | △ | ⊙ | △ | ○ | △ | ○ | ○ | ○ | × | ○ | × | ○ | ○ | △ | ○ | ⊙ | ⊙ |
| Fluorocarbon rubber (FKM) | Standard type (454) | Most superior in heat resistance and good abrasion resistance | -20 180 | ⊙ | ⊙ | ⊙ | ⊙ | ⊙ | ⊙ | ⊙ | ⊙ | △ | × | △ | ⊙ | △ | ⊙ | ○ | × | × | △ | ○ | ⊙ | × | △ | |

Notes 1) Operational temperature means the lip temperature. It should be determined based on ambient temperature, heat generated by the machine, lip friction heat, heat generation by the agitation of the substance to be sealed and heat transferred from other components etc.

2) The highest normal-operation temperature may be lower than indicated in this table, depending on the kind and properties of the substance to be sealed (Refer to Table 1.4.3.)

Table 1.4.3 Upper limits guideline of normal operation temperature of rubber materials used with different oils (°C)

| Rubber material | Gear oil | Turbine oil | Engine oil | ATF |
|-----------------------------|--------------|-------------|------------|-------|
| Nitrile rubber | (100) | 100 | 120 | (120) |
| Hydrogenated nitrile rubber | 140 | ← | ← | ← |
| Acrylic rubber | 150 | ← | ← | ← |
| Silicone rubber | Incompatible | 150 | 170 | (150) |
| Fluorocarbon rubber | 180 | ← | ← | ← |

Remark)
The () indicates oil with extreme pressure additives. Extreme pressure additives are compounds of phosphor, sulfur or chlorine base, added to prevent wear or seizure on sliding or rotating surfaces. These compounds are activated by heat and chemically react against rubber, which deteriorates rubber properties.

Small talk 1

A new salesman's surprise

One day a new staff who only recently joined the sales department received a complaint from a customer. "Your oil seal is leaking . . . it breaks into pieces!"

He checked the actual seal at the customer's site and found it was clayish and broke into pieces when he touched it. The customer was very upset and said, "We chose your expensive silicone seal because it was supposed to be resistant to high

temperature." The salesman confused and then consulted his manager. "This phenomenon is called cure reversion; gear oil shredded the silicone rubber molecules," the manager answered and advised, "Silicone rubber must not be used in gear oil application." Telling this explanation to the customer, the new salesman realized the importance of rubber-oil compatibility through this experience.

(3) Selection of metal case and spring materials

The materials of metal case and spring can be selected according to the substance to be sealed.

Table 1.4.4 Compatibility of metal-case and spring materials with substance to be sealed

| Material Substance to be sealed | Metal case | | Spring | |
|------------------------------------|---|------------------------------------|----------------------------------|-----------------------------------|
| | Cold rolled carbon steel sheet (JIS SPCC) | Stainless steel sheet (JIS SUS304) | High carbon steel wire (JIS SWB) | Stainless steel wire (JIS SUS304) |
| Oil | ○ | – | ○ | – |
| Grease | ○ | – | ○ | – |
| Water | × | ○ | × | ○ |
| Seawater | × | ○ | × | ○ |
| Water vapor | × | ○ | × | ○ |
| Chemicals | × | ○ | × | ○ |
| Organic solvent | ○ | ○ | ○ | ○ |

○ : Compatible × : Incompatible – : Not applicable

1.5 Shaft and housing design

(1) Shaft design

Oil seals can show good sealing performance when mounted on properly designed shafts. To design shafts properly, follow the specifications below.

1) Material

Shafts should be made from carbon steels for machine structural use, low-alloy steel, or stainless steel. Brass, bronze, aluminum, zinc, magnesium alloy and other soft materials are not suitable, except for special applications such as for low-speed or in a clean-environment.

2) Hardness

Shaft hardness should be at least 30 HRC. In a clean environment, shaft hardness does not influence seal performance. However, in an environment where dust or contaminated oil exists, harder shaft is desired.

Hard shaft is advantageous regarding seal damage prevention.

3) Dimensional accuracy

The shaft diameter tolerance should be h8. Seals are designed to suit shafts with the tolerance of h8.

When mounted on other tolerance shafts, seals may be unable to provide sufficient sealing performance.

For use of other tolerance shafts, consult Koyo.

Table 1.5.1 h8 Shaft tolerance

| Nominal shaft diameter <i>d</i> , mm | | Tolerance μm | |
|--------------------------------------|-------|--------------|-------|
| | | h8 | |
| Over | Up to | Upper | Lower |
| 3 | 6 | 0 | -18 |
| 6 | 10 | 0 | -22 |
| 10 | 18 | 0 | -27 |
| 18 | 30 | 0 | -33 |
| 30 | 50 | 0 | -39 |
| 50 | 80 | 0 | -46 |
| 80 | 120 | 0 | -54 |
| 120 | 180 | 0 | -63 |
| 180 | 250 | 0 | -72 |
| 250 | 315 | 0 | -81 |
| 315 | 400 | 0 | -89 |
| 400 | 500 | 0 | -97 |
| 500 | 630 | 0 | -110 |
| 630 | 800 | 0 | -125 |
| 800 | 1 000 | 0 | -140 |

Small talk 2

A service engineer's finding

One customer called, "Some seals show oil leakage and some are OK. Please come and see immediately." A Koyo service engineer visited the customer.

He checked shaft diameter and any damage, also visually checked the seals, but no possible cause of oil leakage was found.

He asked how the shaft surface was finished. It was paper lapped to get the desired level of surface roughness. He then checked the shaft surface and found that the leaking shaft had lead marks (spiral traces of lapping) running in the leaking direction. When he rotated the shaft in the reversing direction, no leakage occurred.

Showing a catalog, he advised the customer to finish shafts by plange cut grinding. Satisfied, he went back and felt it was a good day.

4) Shaft end chamfer

To protect seals from damage at mounting onto shafts, recommended chamfer on the shaft end is shown below.

| Nominal shaft diameter d_1 , mm | | d_1-d_2 mm | Nominal shaft diameter d_1 , mm | | d_1-d_2 mm |
|-----------------------------------|-------|--------------|-----------------------------------|-------|--------------|
| Over | Up to | | Over | Up to | |
| – | 10 | 1.5 min. | 50 | 70 | 4.0 min. |
| 10 | 20 | 2.0 min. | 70 | 95 | 4.5 min. |
| 20 | 30 | 2.5 min. | 95 | 130 | 5.5 min. |
| 30 | 40 | 3.0 min. | 130 | 240 | 7.0 min. |
| 40 | 50 | 3.5 min. | 240 | 500 | 11.0 min. |

Note) When round chamfer is applied, take the above specified d_1-d_2 dimensional chamfer or more.

Fig. 1.5.1 Shaft end chamfer

5) Surface roughness and finishing method

To ensure the sealing performance of seals, the shaft surface to be in contact with the lip should be finished to $(0.63-0.2) \mu\text{mRa}$ and $(2.5-0.8) \mu\text{mRz}$ in roughness.

Note that lead marks on the shaft surface may carry the substance to be sealed in the axial direction during shaft rotation, which interferes with the function of the seal.

Finish shaft surface such that the lead angle will be no greater than 0.05° . To achieve this, plange cut grinding is most suitable. To avoid undulation on the shaft surface, the ratio of shaft rotational speed vs grinding-wheel rotational speed should not be an integer.

■ Good finished surface

■ Undesirable finished surface

The surface shows visible lead marks

Fig. 1.5.2 Shaft surface with and without lead marks

(2) Housing design

1) Material

Steel or cast iron is generally used as the material of housings. When aluminum or plastic housing is used, the following consideration and study are required, as seal seating in housing bore may become loose fitting under high temperature because the housing material and seal material have different linear expansion coefficients. This may cause problems such as leakage through the seal O.D, or seal dislocation.

2) Dimensional accuracy

The housing bore tolerance should be H7 or H8 when bore is 400 mm or less. For larger housing bores, recommended tolerance is H7.

Table 1.5.2 Housing bore tolerance

| Nominal bore diameter D , mm | | Tolerance μm | | | |
|--------------------------------|-------|-------------------------|-------|-------|-------|
| | | H7 | | H8 | |
| Over | Up to | Upper | Lower | Upper | Lower |
| 3 | 6 | +12 | 0 | +18 | 0 |
| 6 | 10 | +15 | 0 | +22 | 0 |
| 10 | 18 | +18 | 0 | +27 | 0 |
| 18 | 30 | +21 | 0 | +33 | 0 |
| 30 | 50 | +25 | 0 | +39 | 0 |
| 50 | 80 | +30 | 0 | +46 | 0 |
| 80 | 120 | +35 | 0 | +54 | 0 |
| 120 | 180 | +40 | 0 | +63 | 0 |
| 180 | 250 | +46 | 0 | +72 | 0 |
| 250 | 315 | +52 | 0 | +81 | 0 |
| 315 | 400 | +57 | 0 | +89 | 0 |
| 400 | 500 | +63 | 0 | – | – |
| 500 | 630 | +70 | 0 | | |
| 630 | 800 | +80 | 0 | | |
| 800 | 1 000 | +90 | 0 | | |
| 1 000 | 1 250 | +105 | 0 | | |
| 1 250 | 1 600 | +125 | 0 | | |

1.5 Shaft and housing design

3) Chamfer

Provide the chamfer at the housing bore inlet as shown below so that a seal can be mounted easily and avoided from damages.

Shouldered bore

Straight bore

Unit mm

| Seal width, b | | B_1 min. | B_2 min. | L |
|-----------------|-------|---------------|---------------|-----|
| Over | Up to | | | |
| – | 10 | $b + 0.5$ | $b + 1.0$ | 1.0 |
| 10 | 18 | $b + 0.8$ | $b + 1.6$ | 1.5 |
| 18 | 50 | | | |

Fig. 1.5.3 Recommended housing bore chamfers

4) Housing shoulder diameter

In case the housing bore has a shoulder, satisfy the following dimensional requirements.

| Nominal seal O.D, D | | F |
|-----------------------|-------|---------|
| Over | Up to | |
| – | 50 | $D - 4$ |
| 50 | 150 | $D - 6$ |
| 150 | 400 | $D - 8$ |

Fig. 1.5.4 Recommended housing shoulder diameters

5) Surface roughness

To ensure seal sitting and to prevent leakage through seal O.D, finish bore surface to the roughness specified below.

Table 1.5.3 Housing bore surface roughness

| Seal type | Housing bore surface roughness |
|-------------------------------|---|
| For metal O.D wall type seal | (3.2~0.4) μmRa |
| | (12.5~1.6) μmRz |
| For rubber O.D wall type seal | (3.2~1.6) μmRa (12.5~6.3) μmRz |

6) Seals with coated metal O.D wall are available in case metal O.D wall type seals with extremely high sealing performance are required.

Consult Koyo for these oil seals.

(3) Total eccentricity

When the total eccentricity is excessive, the sealing edge of the seal lip cannot accommodate shaft motions and leakage may occur.

Total eccentricity is the sum of shaft runout and double the housing-bore eccentricity. It is normally expressed in TIR (Total Indicator Reading).

Shaft runout is defined as being twice the eccentricity between the shaft center and shaft rotation center.

This is also normally expressed in TIR.

Fig. 1.5.5 Shaft runout

Housing bore eccentricity is defined as being the eccentricity between the housing-bore center and shaft rotation center. It is generally expressed in TIR (Total Indicator Reading).

Fig. 1.5.6 Housing bore eccentricity

(4) Allowable total eccentricity

The allowable total eccentricity is the maximum total eccentricity at which the sealing edge can accommodate shaft rotation and retain adequate sealing performance. The allowable total eccentricity of seals is dependent not only on seal characteristics, such as seal type, seal size, and rubber material, but also on other conditions, including shaft diameter tolerance, temperature and rotational speed.

It is therefore difficult to determine the allowable total eccentricity of individual seals. The typical allowable total eccentricity values of seals are shown in Fig. 1.5.7.

Fig. 1.5.7 Allowable total eccentricity for oil seal

1.6 Seal characteristics

(1) Seal service life

The seal service life is defined at the time reached to insufficient seal performance, by the lip rubber abraded, chemically deteriorated or hardened.

It is not so easy to determine actual seal service life, because it is dependent on many factors, such as condition of operational temperature, eccentricity,

rotational speed, substance to be sealed, and lubrication.

The diagram below (Fig. 1.6.1) shows the curves of estimated seal service life, obtained using major life-determining conditions as parameters, such as rubber material, lubricant, and lip temperature. Approximate seal life can be determined from this diagram.

Fig. 1.6.1 Oil seal service life estimation curves

(2) Lip temperature

To determine the seal service life based on the above diagram, it is critical to estimate lip temperature precisely.

As the shaft rotates, the seal lip is heated due to friction. Lip temperature is dependent on the balance between the energy supplied by frictional heat and the radiated energy, which varies according to temperature

difference and the construction surrounding the seal.

Many factors influence lip temperature, so complicated calculation is required to determine this precisely.

The following is the procedure for estimation of lip temperature.

● Lip temperature estimation method

- ① Calculate the shaft surface speed using the following equation

$$v = \frac{\pi dn}{(60 \times 1\,000)}$$

where,

- v : Shaft surface speed, m/s
- π : Ratio of circle circumference to diameter (3.14)
- d : Shaft diameter, mm
- n : Rotational speed, min^{-1}

- ② Determine the supposed ambient temperature
- ③ Find the point at which the ambient temperature curve meets the calculated shaft surface speed in Fig. 1.6.2
- ④ Read the ordinate value of the point
- ⑤ Obtain the estimated lip temperature by the sum of the ordinate value and ambient temperature

Example

Shaft diameter: 50 mm

Rotational speed: 4 000 min^{-1}

Ambient temperature: 80 °C

Shaft surface speed can be obtained as follows;

$$v = \frac{\pi \times 50 \times 4\,000}{60 \times 1\,000} = 10.5 \text{ m/s}$$

In Fig. 1.6.2, the cross of the curve for ambient temperature 80 °C and shaft surface speed 10.5 m/s indicates that the lip temperature rise will be 20 °C.

Therefore, lip temperature is estimated 100 °C (80 + 20 = 100 °C).

Fig. 1.6.2 Estimated lip temperature rise curves

(3) Allowable shaft surface speed

The sealing edge of the seal should provide constant sealing performance, maintaining contact with the shaft while accommodating shaft runout and housing bore eccentricity.

When shaft rotation is extremely fast, the sealing edge eventually becomes unable to accommodate shaft runout and housing bore eccentricity, thus deteriorating sealing performance. The speed just before the sealing performance is deteriorated, is called the allowable shaft surface speed for seals.

The allowable shaft surface speed for seal is mostly influenced by shaft runout. When total eccentricity is small, the allowable shaft surface speed is a constant value, depending on the rubber material and seal type.

The diagrams below show the typical allowable shaft surface speed for seals mounted on the shaft and housing that are finished to a given level of accuracy.

Fig. 1.6.3 shows the typical allowable shaft surface speed for seals of different rubber materials. Fig. 1.6.4 shows the typical allowable shaft surface speed for various types of nitrile-rubber seals.

Fig. 1.6.3 Relation between rubber materials and allowable shaft surface speed for seal

Fig. 1.6.4 Relation between seal types and allowable shaft surface speed for seal

(4) Allowable internal pressure

Another factor that may deteriorate seal performance is internal pressure. The allowable internal pressure is also significantly dependent on shaft runout and housing bore eccentricity.

The diagram below (Fig. 1.6.5) shows typical allowable internal pressure under the given accuracies of shaft and housing.

Fig. 1.6.5 Allowable internal pressure for seal

Small talk 3

A precious experience for a new salesman

"The oil seal melts down and oil leaks!"

Receiving an urgent phone call from a customer, a new salesman at Koyo left the office immediately, believing that something critical had happened.

At the customer's site, the lip was abraded significantly and the rubber did look molten. The customer suspected that the material was the cause of the problem.

Browsing the catalog confusedly, he questioned the customer, remembering the sales-training lectures he had attended before. "How did you lubricate the seal before its initial use?"

Suspecting that insufficient initial lubrication might be the cause, he instructed the customer to coat grease around the lip and run the machine.

Two hours passed, and the seal still showed no leakage. An overhaul proved that the seal was in good condition, with negligible lip abrasion.

"I now thoroughly understand the importance of pre-lubrication," said the customer. It was a precious experience for the salesman as well.

(5) Seal torque

The seal torque is determined by lip radial load, coefficient of friction, and shaft diameter, and can be calculated by the following equation:

$$T = \frac{1}{2 \times 1000} \mu d R_L$$

where,

T : Seal torque, N · m

μ : Coefficient of friction at sealing edge

d : Shaft diameter, mm

R_L : Seal radial load, N

Seal radial load is determined by three factors: a component of stress caused by circumferential lip elongation that occurs when the seal is mounted on a shaft, a component of stress caused by deflection at the lip base, and a component of spring load (Fig. 1.6.6).

Fig. 1.6.6 Factors of seal radial load

The coefficient of friction at the sealing edge varies significantly depending on the seal lubricant type and shaft surface speed. It is difficult to calculate seal torque accurately. Consult Koyo for this calculation.

1) Initial seal torque

Seal torque may be very high just after the seal mounting on a machine. However, it will become stable low torque within one or two hours (Fig. 1.6.7).

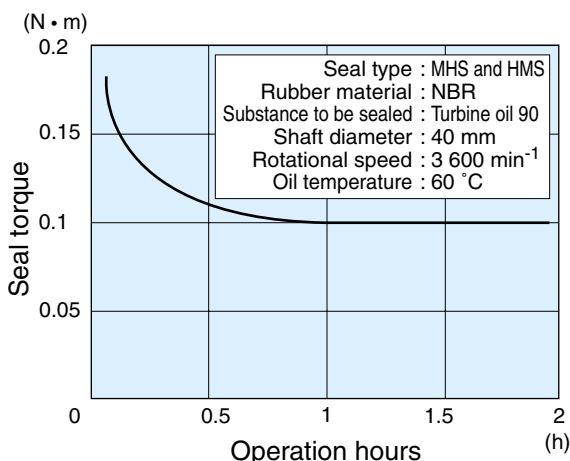

Fig. 1.6.7 Seal torque change with passing time

Initial high torque occurs while the coefficient of shaft-lip friction is unstable. As operation continues, the shaft and lip become running in each other, it stabilizes the friction coefficient and seal torque.

2) Factors for seal torque

Fig. 1.6.8 shows how rotational speed and lubricant influence seal torque. As this diagram shows, generally seal torque increases in proportion to shaft rotational speed increase. High viscosity lubricating oil also increases seal torque.

Fig. 1.6.8 Relation between rotational speed and seal torque

Fig. 1.6.9 shows how shaft diameter influences seal torque. The larger shaft diameter, the higher the seal torque correspondingly.

Fig. 1.6.9 Relation between shaft diameter and seal torque

Small talk 4

A discovery on a cold day

A second-year Koyo sales rep received a harsh complaint from a customer. "Oil seals cannot be easily mounted today! When we press-fit them, the rubber tears."

He checked the seal at the customer's site, but could not find the reason. Then he consulted his manager by phone for advice.

"The seal is having a 'cold'," his manager responded. "Like humans, seals do not enjoy a cold environment. Tell them to warm up the room and try again." Following this advice, a stove was carried into the assembly shop and the seal was tried to remount after being slightly heated. To the surprise of the customer as well as the sales rep, the seal could be mounted smoothly without any problem.

The customer was very grateful to him. "Thank you for dealing with the problem. We also can now work in a warm environment." The sales rep returned to the office, feeling very proud of himself.

Back in the office, he heard another good piece of news from a material engineer: "Recent Koyo oil seals are made of improved material and can operate well in cold environments."

1.7 Handling of seal

Carelessness in seal handling may cause oil leakage. Correct action should be taken for good inwards, storage, transportation, handling and mounting.

(1) Storage

Follow the instructions below in the storing.

- Keep seals: Room temperature Max.30 °C and humidity 65 % or less. In hard box to avoid dust or sands or deformation
- Keep rule: First in first out
- Avoid: Direct/indirect ray of sun, ozone
- Do not over stack paper-made packages. Those at the bottom of the stack may become deformed due to weight.

(2) Handling

Keep the following cautions at handling.

- Do not damage seals by knife or screw driver when opening wrap.
- Do not place seals for long time on table without sheet cover, due to chance of dust or sand adhesion.
- Do not hang by wire, string, or nail, which deforms or damages seal lip.
- Do not use cleaners, solvents, corrosive fluids, or chemical liquid. Use kerosene when washing seals.

(3) Mounting

- 1) Before mounting, confirm that there is no damage, no dirt or foreign particles on the seals.
- 2) Apply suitable, clean lubricant to the seal lip for initial lubrication. For oil seals with a minor lip, pack clean grease between main lip and minor lip (Fig. 1.7.1).

Fig. 1.7.1 Prelubrication for seals with minor lip

3) Recommended grease

- Small penetration (soft grease)
 - Small penetration change by temperature
 - Wide serviceable temperature range
 - Lithium base type (avoid silicone base grease for silicon rubber seal, urea base grease for fluoroc rubber seal which may harden or deteriorate seal rubber)
- 4) When seal is mounted at cold area, warm seal up to have seal flexibility and then mount it.
 - 5) To avoid damage on seal lip and shaft surface when seal is mounted onto shaft. Shaft edge should be chamfered or 0.2 mm smaller guide as illustrated below (Fig.1.7.2).

Fig. 1.7.2 Recommended shaft profile and machine construction to avoid damaging shaft surface

6) When seal is pressed into housing bore, use pressing jig as shown in Fig. 1.7.3.

Fig. 1.7.3 Recommended seal press-fitting jigs

Seal press fit at a slant may cause the fit surface to have tear or scuffing and leakage. To ensure good sealing performance, seals need to be mounted at right angles to shafts. For right angled mounting, press the seal down thoroughly to reach the housing shoulder (Fig. 1.7.4).

Fig. 1.7.4 Seal press-fitting jig for shouldered housing bore

To mount seal into a straight housing bore, the jig should be contacted with the machine-finished surface to mount the seal at right angles to the housing bore (Fig. 1.7.5).

Fig. 1.7.5 Seal press-fitting jig for straight housing bore

In the case of O.D wall being rubber, press the seal into housing by constant pressure 2-3 times at a constant speed to prevent spring back.

Fig. 1.7.6 shows typical seal pressing load required to press-fit an oil seal into the housing. Refer to the shown data when press-fitting oil seals.

Based on these diagrams, decide a slightly higher pressing load.

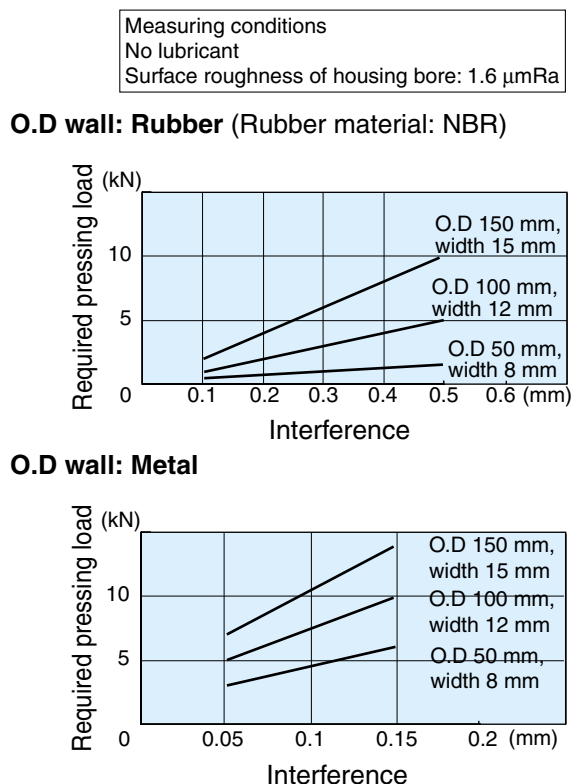

Fig. 1.7.6 Relation between required seal pressing load and seal interference

1.7 Handling of seal

7) In case of shaft has spline, keyway, or holes, use seal protecting jig to prevent lip damage as illustrated below (Fig. 1.7.7).

If difficult to use jig, remove sharp corners, round the edges and coat enough grease.

Fig. 1.7.7 Seal protecting jig for spline, keyway, holes on shaft

Use a protecting jig made from steel or stainless steel. All the corners of the jig should be chamfered.

Do not use a jig made from soft material such as aluminum; such a jig is prone to damages and a damaged jig may scratch the seal lip.

8) When heavy housing with seal is assembled with shaft, or when long or heavy shaft is inserted into seal, seal damage should be avoided. Use the following guide jig to get centering (Figs. 1.7.8 and 1.7.9).

Fig. 1.7.8 Guide jig for inserting of long shaft into seal bore

Fig. 1.7.9 Guide jig for mounting of heavy housing with seal onto shaft

If these methods cannot be applied, assemble shaft and housing first, then mount seal.

9) When oil seal is replaced, use a new seal.

Contact position of new seal lip on the shaft should be displaced to 0.5 mm (1~2 mm for large-size seals) from the old seal lip contact position by applying spacer as illustrated below (Fig. 1.7.10).

Fig. 1.7.10 Avoid old seal lip track

(4) Mounting of split MS-type seals

MS-type seal has one split in order to have easy mounting on to long shaft or complicated shaped shaft (Fig. 1.7.11).

After mounting, it is not needed to use adhesive bond, but if it looks to be bonded, connect correctly not to produce a step around the seal lip.

Fig. 1.7.11 MS-type seal with one split

Mount a split MS-type seal on to the shaft as following procedure:

- ① Mount the spring first and connect spring by the hook (Fig. 1.7.12).
- ② Mount the seal and position split area to upwards on the shaft.
- ③ Place the spring on the seal spring groove, position spring joint area to 45° apart from seal split area.
- ④ Fix the seal by seal fixing ring. If seal fixing ring is split type, avoid position of ring split area from seal split area.

Fig. 1.7.12 Spring hook connection

(5) Cautions after mounting

- 1) If the area near the oil seal is painted, make sure to keep the seal lip and the shaft area in contact with the lip free from paint.
- 2) Avoid cleaning on the mounted seal area as much as possible. If cleaning is inevitable, perform it quickly and wipe off the detergent immediately when completed.

Small talk 5

A murmur of a female staff member

One day, a female staff member over-heard a conversation:

Third-year sales rep: "The rubber of oil seals is petroleum-based (naphtha-base), isn't it?"

Engineering leader: "Nitrile rubber and acrylic rubber are synthetically produced based on naphtha, but silicone rubber is made from silicon, which can be found naturally. Fluorocarbon rubber is produced synthetically from fluorine compounds extracted from fluorite, which is known for its fluorescent light emission."

"Oh, how knowledgeable our engineering leader is!" murmured the female staff member, impressed.

1.8 Causes of seal failures and countermeasures

(1) Causes of seal failures

To identify the causes of seal failure and take proper measures, it is critical to observe the seal lip closely and

evaluate the failure in all respects, such as shaft surface roughness, contaminants and lubrication. Causes of major seal failure are listed below (Table 1.8.1).

Table 1.8.1 Causes of seal failures

| Factor | | | | |
|---|--|-------------------------------|----------------------------|--------------------|
| 1st | 2nd | 3rd | 4th | 5th |
| Leakage from seal | From lip | Damages on lip | Burrs on shaft chamfer | |
| | | Spline, keyway on shaft | | |
| Entry of foreign materials | | | | |
| Wrong handling | | | | |
| Lip turned backward | | Small shaft chamfer | | |
| Center off set at mount | | | | |
| Excessive inside pressure | | | | |
| Missing spring | | Small shaft chamfer | | |
| Center off set at mount | | | | |
| Caused by Stick slip* | | | | |
| Lip hardened | | High oil temperature | | |
| Poor lubrication | | | | |
| Excessive inside pressure | | | | |
| Lip softened | | Improper rubber | | |
| Long time dip in cleaner, solvent | | | | |
| Heavy wear on shaft | | Entry of foreign materials | | |
| Chemical wear | | | High oil temperature | |
| Poor lubrication | | | Extreme pressure additives | |
| Caused by Stick slip* | | | | |
| Heavy wear on lip | Poor lubrication | | | |
| Excessive internal pressure | | | | |
| Rough shaft surface finish | | | | |
| Entry of foreign materials | | | | |
| Uneven wear on lip | Excessive eccentricity at mount | | | |
| Inclined seal mounting | | | | |
| Rough face, Steaks on lip | Entry of foreign materials | | | |
| Poor lubrication | | | | |
| Tear at seal heel bottom | Wrong handling | | | |
| Reaction by impact pressure | | | | |
| Excessive inside pressure | | | | |
| Lip deformation (small interference) | High oil temperature | | | |
| Lip face contact | Excessive inside pressure | | | |
| Minus pressure between lips | | | | |
| Big shaft runout | | | | |
| Larger shaft diameter | | Poor lubrication | | |
| Caused by Stick slip* | | Improper rubber | | |
| Reaction by impact pressure | | | | |
| No abnormality on seal | Smaller shaft diameter | | Small interference | |
| Improper shaft roughness | | | | |
| Damages on shaft | | | | |
| Lead machining on shaft | | | | |
| Poor lip followability | | Big shaft runout | | |
| Big eccentricity | | | | |
| Small interference | | | | |
| Lip high rigidity | | | | |
| Poor low temperature resistance | | | | |
| Wrong direction of seal mounting | | | | |
| Adhesion of foreign particles at mounting | | | | |
| From seal O.D side | Peeling, Scuffing, Damages, Deformation, Inclined mounting | Smaller housing bore diameter | | Large interference |
| Small housing bore chamfer | | | | |
| Rough housing bore surface finish | | | | |
| Improper mounting tool | | | | |
| No abnormality on seal | Larger housing bore | | Small interference | |
| Smaller seal O.D | | Small interference | | |
| Rough housing bore surface finish | | | | |
| Damages or blowholes on housing bore | | | | |
| Wrong direction of seal mounting | | | | |

* Stick slip:
 A friction related phenomena in which the sealing element tends to adhere and rotate with the shaft surface momentarily until the elastic characteristics of the sealing element overcome the adhesive force, causing the seal lip to lose contact with the rotating shaft long enough to allow leakage.
 This cycle repeats itself continuously and is normally associated with non-lubricated and boundary-lubricated conditions.

(2) Causes of seal failures and countermeasures

Table 1.8.2 below lists the possible causes of seal failures and countermeasures.

Table 1.8.2 Causes of seal failures and countermeasures (1)

Oil leakage from lip (1)

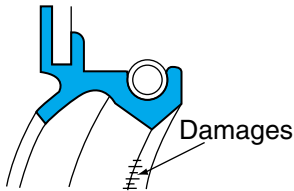

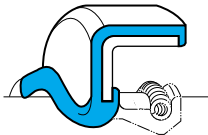

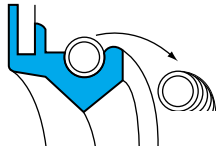

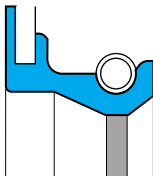

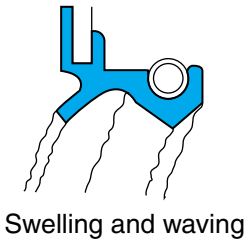

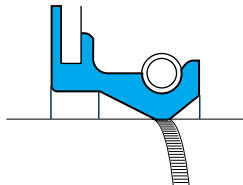

| Symptom | Phenomenon | Causes | Countermeasures |
|---------------------|---|--|--|
| Damages on lip |  | <ol style="list-style-type: none"> 1) Sharp edge or burrs on shaft chamfer 2) Shaft spline or keyway 3) Entry of foreign materials 4) Poor handling | <ul style="list-style-type: none"> • Remove burrs and polish • Use shaft protecting jig (See Fig. 1.7.7 on page 28.) • Clean work shop • Improve handling manner (Consult Koyo.) |

YS type
d₁ 220~(340)

YS YSN YSA YSAN

Remarks

- 1) For seals marked ○, Koyo owns molding dies for production.
- 2) Seal number is constructed by combination of type code and dimensional numbers (bore diameter, outside diameter and width).
Example: YS32036018 (320X360X18 mm).
- 3) Seal number marked ○* have suffix -1.
- 4) Seals with spacers are available.
Seal number with spacers is referred on right side page.
- 5) Rubber code N represents nitrile rubber, F: fluorocarbon rubber, and K: hydrogenated nitrile rubber.

MORGOIL seals

d_1 167~1 593

MS..J MS..NJ H..J H..JM H..PJ

■ Mounting example

Remark) All seals use nitrile rubber.

Note 1) Special type code B represents "with a steel band" and W represents "with a wire."

WR...RJ MH...J H...J

Remarks

- 1) All seals use nitrile rubber.
- 2) Consult Koyo for drain-provided seals.

Water seals

d_1 219.2~1 460

XMH XM XMHE

- Remarks
- 1) For seals marked ○, Koyo owns moulding dies for production.
 - 2) Seal number is constructed by combination of type code and dimensional numbers (bore diameter, outside diameter and width). Example: XMHE77081029 (770×810×29 mm)
 - 3) All seals use nitrile rubber.

2.1 O-ring classification and application guide

(1) O-ring classification and application guide

O-rings are used in a various machines as a compact sealing component. O-rings can generally be classified into dynamic applications ("packing") and static appli-

cations ("gaskets").

Other classification is according to their properties, such as oil resistance. O-rings are specified in the industrial standards listed in Table 2.1.1.

Table 2.1.1 O-ring classification and application guide

| Application | General industrial machines | | Automobiles | Aircraft | | |
|----------------------|---|-----------------------------------|--|------------------------------|-----------------------------------|---|
| Applicable standards | JIS B 2401 | | JASO F 404 | AS 568 AN 6227 AN 6230 | | |
| Classification | Class | Remarks | Remarks | Class | Remarks | Remarks |
| Material | Class 1-A | For mineral oil (A70)* | For mineral-base fluids Class: JIS Class 1-A (A 70)* | Class 1-A | For general mineral oil | For mineral-base fluids Class: JIS Class 1-A (A 70)* JIS Class 1-B (A 90)* JIS Class 4-D |
| | Class 1-B | For mineral oil (A90)* | | Class 2 | For gasoline | |
| | Class 2 | For gasoline | | Class 3 | For brake fluid | |
| | Class 3 | For animal oil and vegetable oil | | Class 4-C | For high temperature applications | |
| | Class 4-C | For high temperature applications | | Class 4-D | For high temperature applications | |
| Class 4-D | For high temperature applications | Class 4-E | For high temperature applications | | | |
| Class 5 | | Class 5 | For coolant | | | |
| Remarks | P: For dynamic / static sealing G: For static sealing V: For vacuum flanges S: For static sealing (not standardized in the JIS) | | For general industrial use | For dynamic / static sealing | | AS 568 : For static sealing AN 6227 : For dynamic / static sealing AN 6230 : For static sealing |

*: Hardness measured by durometer type A

(2) Backup ring types and material

Backup rings are used with O-rings to prevent O-ring protrusion from the groove.

Backup rings are used for dynamic sealing and for static sealing of cylindrical surface.

Table 2.1.2 shows backup ring types and material.

Fig. 2.1.1 O-ring installation with backup rings

Table 2.1.2 Backup ring types and material

| Applicable standard | JIS B 2407 | | |
|---------------------|---|-------------------|------------------|
| Type | T1: Spiral ring | T2: Bias-cut ring | T3: Endless ring |
| Shape | | | |
| Material | Tetrafluoroethylene (resin) | | |
| Applications | For dynamic sealing / static sealing of cylindrical surface | | |

2.2 Designation numbers

(1) O-ring designation numbers

O-ring designation number consists of material code, application code, and dimensional code.

Table 2.2.1 O-ring numbering system

| Example | | |
|-----------|--------------|--|
| P | 26 | JIS product ¹⁾ |
| 1B | G | 80 JIS product |
| 2 | JASO | 1013 JASO product ²⁾ |
| 4C | AS | 325 AS product ³⁾ |
| B | 0212G | ISO product ⁴⁾ |

| | |
|--|---|
| | <p>Notes</p> <p>1) JIS: Japanese Industrial Standards</p> <p>2) JASO: Japanese Automobile Standard Organization</p> <p>3) AS: Aeronautical Standard</p> <p>4) ISO: International Organization for Standardization</p> |
|--|---|

1) Material codes

| Code | Basic standard | Remarks |
|-------------|----------------------|-------------------------------------|
| None | JIS B 2401 Class 1-A | Nitrile rubber (A70)* |
| 1B | JIS B 2401 Class 1-B | Nitrile rubber (A90)* |
| 2 | JIS B 2401 Class 2 | Nitrile rubber (gasoline-resistant) |
| 3 | JIS B 2401 Class 3 | Styrene-butadiene rubber |
| 4C | JIS B 2401 Class 4-C | Silicone rubber |
| 4D | JIS B 2401 Class 4-D | Fluorocarbon rubber |
| 4E | JASO F 404 Class 4-E | Acrylic rubber |
| 5 | JASO F 404 Class 5 | Ethylene propylene rubber |

* : Hardness measured by durometer type A

2) Application codes

| Code | Basic standard | Remarks |
|--|----------------|---|
| P | JIS B 2401 P | For dynamic sealing / static sealing of cylindrical or flat surface |
| G | JIS B 2401 G | For static sealing of cylindrical or flat surface |
| V | JIS B 2401 V | For vacuum flange |
| S | Slim series | For static sealing of cylindrical or flat surface |
| JASO | JASO F 404 | For dynamic sealing / static sealing of cylindrical or flat surface |
| AS | AS 568 | For static sealing of cylindrical or flat surface |
| | AN 6227 | For dynamic sealing / static sealing of cylindrical surface |
| | AN 6230 | For static sealing of cylindrical surface |
| A B C D E | ISO 3601 | For general industrial machines |

(2) Backup ring designation numbers

Backup ring number consists of type code and the O-ring number for which the backup ring is applied.

Table 2.2.2 Backup ring numbering system

| Example | |
|-----------|-----------|
| T1 | P5 |

| |
|--|
| |
|--|

■ Type codes

| Code | Backup ring shape |
|-----------|-------------------|
| T1 | Spiral |
| T2 | Bias-cut |
| T3 | Endless |

Remark) Backup ring types and shapes are listed in Table 2.1.2.

2.3 Selection of O-ring

(1) O-ring materials

Materials conforming to JIS B 2401 or JASO F 404 standards are mainly used. Major rubber materials and their physical properties are listed in Table 2.3.1.

Consult Koyo for special materials to suit a wide variety of applications.

Table 2.3.1 O-ring rubber materials and their physical properties

| Applicable standards | | JIS B 2401 | | | | | - | | | - |
|------------------------------------|--|---|----------------------|--------------------------------|--------------------------------|----------------------------------|-----------------------------------|------------------------------|----------------------------------|---------------------------|
| | | JASO F 404 | - | JASO F 404 | | | - | | | |
| Class | | Class 1-A | Class 1-B | Class 2 | Class 3 | Class 4-C | Class 4-D | Class 4-E | Class 5 | |
| Rubber materials | | Nitrile rubber (NBR) | Nitrile rubber (NBR) | Nitrile rubber (NBR) | Styrene-butadiene rubber (SBR) | Silicone rubber (VMQ) | Fluorocarbon rubber (FKM) | Acrylic rubber (ACM) | Ethylene-propylene rubber (EPDM) | |

2.3 Selection of O-ring

(2) Selection of O-ring material

O-rings have contact with substances to be sealed. Therefore, material should be chemically stable to such substances.

Table 2.3.2 below lists the substances with which each rubber material can remain stable. Consult Koyo for further details.

- ⊙ : Resistant to the substance
- : Resistant to the substance except under extreme conditions
- △ : Not resistant to the substance except under specific favorable conditions
- × : Not resistant to the substance

(3) Selection of O-ring cross section diameter

The groove into which an O-ring is installed is designed to compress (squeeze) the cross section diameter. Determine this compression carefully, because O-rings may become permanently deformed if squeezed excessively, thus deteriorating sealing performance.

Generally, the compression of an O-ring should be between 8 % and 30 % in ring cross section diameter (the lower limit of 8 % for sufficient sealing performance and the upper limit of 30 % for limited compression set.).

Fig. 2.3.1 shows the relation between O-ring cross section diameter and compression set.

Fig. 2.3.1 Relation between O-ring cross section diameter and compression set

Larger cross section diameter offers more stable sealing performance. As shown in Fig. 2.3.1, when the O-ring compression rate is constant (25 % in the figure), the larger cross section diameter shows the smaller the compression set. Larger cross section diameter is advantageous in that it can accommodate errors in installation dimensions as well.

In dynamic-sealing applications, larger cross section diameter is less likely to twist during service or during installation. The largest cross section diameter possible should be selected providing it can fit in the available space.

2.4 O-ring technical principles

(1) Sealing mechanism

Fig. 2.4.1 shows how O-ring can be deformed under pressure.

Fig. 2.4.1 O-ring deformation under pressure

O-ring installed in a groove with compression of 8 % to 30 % provides a self-seal by its elasticity when the pressure is low.

When operation pressure is higher, the O-ring is pressed against one side of the groove, providing better sealing. However, under extremely high pressure, the O-ring partially is pressed out from groove into the gap and may be damaged, and deteriorated sealing performance.

For such high-pressure applications, one or two backup rings should be applied to prevent extrusion into gap.

(2) Backup ring

Backup rings are used for dynamic sealing and for static sealing of cylindrical surface.

Two backup rings should be installed when high pressure is put on the O-ring in two directions. One backup ring is installed when high pressure is applied in one direction.

Even when extrusion into gap does not occur under low pressure, backup rings are recommended because they can extend O-ring service life by preventing O-ring tearing or damage, which are the most common causes of O-ring failures.

One each backup ring is installed on both sides of O-ring normally (total is two backup rings). However, if space does not allow this, one backup ring should be installed on the lower-pressure side.

The O-ring extrusion varies depending on applied pressure, O-ring hardness and gap amount on the cylindrical surface. Refer to Fig. 2.5.1, "O-ring extrusion limit values," when using backup rings.

Backup rings of endless design (T3) are the most advantageous in the prevention of extrusion into the gap. However, those of spiral design (T1) and bias-cut design (T2) can be more easily installed.

All Koyo backup rings are made from tetrafluoroethylene (PTFE) resin, which is chemically stable to all media under a wide range of temperatures and is resistant to corrosion.

(3) O-rings for dynamic sealing (Reciprocal movement)

When fitting groove is provided on the piston, use two O-rings to ensure improved service life and sealing performance (Fig. 2.4.2). Pack grease between the two O-rings in a non-lubrication application. Recommended grease is lithium soap base with NLGI No. 2.

When fitting groove is provided on the cylinder, use a dust seal as well and pack grease between the O-ring and dust seal.

Groove on piston

Groove on cylinder

Fig. 2.4.2 Typical installation of O-ring for dynamic sealing

For the installation of O-rings on cast cylinders or for low-friction dynamic-sealing applications, consult Koyo.

(4) O-rings for static sealing of cylindrical surface

When O-ring is used under low pressure with the compression close to the minimal of 8 %, the fitting groove accuracy affects sealing performance so much, so that the groove accuracy should be controlled at the same level as the fitting groove of dynamic sealing.

Even when an O-ring is selected in accordance with the dimensional table values and groove dimensions, the O-ring may become slack due to dimensional deviation and installation method, which may be caused by the reason why the O-ring is unduly caught between the groove and housing (Fig. 2.4.3).

Fig. 2.4.3 O-ring slack and clogging

Especially large size O-rings must be installed with care to avoid ring slack.

To prevent ring slack for the ring size of 150 mm or more, a slightly smaller size O-ring may be used rather than one that exactly fits the groove dimensions after determining the O-ring compression amount carefully. Consult Koyo for this method.

(5) O-rings for static sealing of flat surface

Determine the O-ring compression amount to be slightly larger than in other applications.

If the O-ring is exposed to internal pressure, the O-ring outside diameter should be determined, according to groove diameter d_7 . When the O-ring is exposed to external pressure, O-ring bore diameter should be determined according to groove diameter d_8 (see Fig. 2.4.4 (a) and (b)).

If the O-ring is exposed to pressure in one direction, the groove side face on the high-pressure side can be eliminated for easy machining (Fig. 2.4.4 (c)).

In this case, dimension B should be greater than the minimum of the groove width b used in flat surface static-sealing application.

(a) For internal pressure

d_7 : Groove O.D
 b : Groove width

(b) For external pressure

d_8 : Groove I.D
 b : Groove width

(c) For internal pressure

B : Seat width

Fig. 2.4.4 Fitting groove for static sealing of flat surface

In the case of internal-pressure applications and O-ring size is small (30 mm or less), the d_7 dimension should be 0.2 to 0.3 mm larger to ensure correct O-ring installation.

In the case of thin O-ring (cross section diameter 3 mm or less) of large size (150 mm or more), it may be installed on the groove incorrectly and partially protruding from the groove, which results in cutting off of O-ring. Such a situation must be avoided. Use thicker O-ring to prevent such a protrusion (Fig. 2.4.5).

For internal pressure For external pressure

Fig. 2.4.5 O-ring protrusion

(6) O-rings for vacuum flanges

In vacuum applications, O-rings are used to seal in gases. Therefore, fitting groove surfaces should be carefully machined and finished.

To select a suitable rubber material to meet vacuum grade, consult Koyo.

(7) Installation in triangular groove

When O-ring is installed on the interior angle on a shaft or flange, the A dimension of the triangular groove should be 1.3 to 1.4 times of the O-ring cross section diameter (Fig. 2.4.6).

Fig. 2.4.6 Triangular-groove dimensions

2.5 Fitting groove design for O-ring

(1) Compression amount

Table 2.5.1 lists the JIS-standard of O-ring compression amount.

See dimension table for each groove dimensions corresponding to O-ring number.

Table 2.5.1 O-ring compression amount

| O-ring number | O-ring dimensions, mm | | Compression amount | | | | | | | |
|---------------------|------------------------------|---------------------|--|------|-------|------|------------------------------------|------|------|------|
| | | | For dynamic sealing /static sealing of cylindrical surface | | | | For static sealing of flat surface | | | |
| | Cross section diameter d_2 | Bore diameter d_1 | mm | | % | | mm | | % | |
| | | | Max. | Min. | Max. | Min. | Max. | Min. | Max. | Min. |
| P3 ~ P10 | 1.9 ±0.08 | 2.8 ~ 9.8 | 0.48 | 0.27 | 24.2 | 14.8 | 0.63 | 0.37 | 31.8 | 20.3 |

| P71 ~ P125 | | 70.6 ~ 124.6 | | | | | | | | |
| P130 ~ P150 | | 129.6 ~ 149.6 | | | | | | | | |
| P150A ~ P180 | 8.4 ±0.15 | 149.5 ~ 179.5 | 1.05 | 0.65 | 12.3 | 7.9 | 1.70 | 1.30 | 19.9 | 15.8 |
| P185 ~ P300 | | 184.5 ~ 299.5 | | | | | | | | |
| P315 ~ P400 | | 314.5 ~ 399.5 | | | | | | | | |
| G25 ~ G40 | 3.1 ±0.1 | 24.4 ~ 39.4 | 0.70 | 0.40 | 21.85 | 13.3 | 0.85 | 0.55 | 26.6 | 18.3 |
| G45 ~ G70 | | 44.4 ~ 69.4 | | | | | | | | |
| G75 ~ G125 | | 74.4 ~ 124.4 | | | | | | | | |
| G130 ~ G145 | | 129.4 ~ 144.4 | | | | | | | | |
| G150 ~ G180 | 5.7 ±0.13 | 149.3 ~ 179.3 | 0.83 | 0.47 | 14.2 | 8.4 | 1.28 | 0.92 | 22.0 | 16.5 |
| G185 ~ G300 | | 184.3 ~ 299.3 | | | | | | | | |

Tolerances of O-ring bore diameter d_1 are given in the dimensional table of the O-rings.

(2) Extrusion into gap from fitting groove

O-ring extrusion into gap from fitting groove on cylindrical surface is related to the gap amount of the cylindrical surface. Pressure of fluid to be sealed or O-ring hardness also influence.

Fig. 2.5.1 shows the relation between these factors.

1. Without backup ring
2. Cylinder expansion due to pressure is not included.
3. These results were obtained after 100 thousand cycles at 2.5 Hz between zero pressure to the pressure specified in the diagram.

Fig. 2.5.1 O-ring extrusion limit values

The values in the above diagram do not include cylinder expansion. If cylinder expansion should be considered due to high pressure, the gap should be 75 % of the values shown in the diagram.

If the gap is larger than the values shown in the diagram, use backup rings.

(3) Fitting groove surface roughness

Fitting groove surface should be finished as specified in Table 2.5.2 below for the O-ring to have sufficient sealing performance and long service life, and to minimize frictional resistance.

Table 2.5.2 O-ring fitting groove surface roughness

| Location | Purpose | Type of pressure | Surface roughness | | |
|-------------------------------|-----------------|---------------------|---------------------|-------|------|
| | | | μm Ra | μm Rz | |
| Groove side and bottom | Static sealing | Constant | Flat surface | 3.2 | 12.5 |
| | | Pulsating | Cylindrical surface | 1.6 | 6.3 |
| | Dynamic sealing | With backup rings | 0.8 | | |
| | | Without backup ring | | 1.6 | 6.3 |
| O-ring sealed contact surface | Static sealing | Constant | — | 0.8 | 3.2 |
| | Dynamic sealing | — | 0.4 | 1.6 | |
| | | — | 0.8 | 3.2 | |
| Chamfer area | — | — | 3.2 | 12.5 | |

(4) Chamfer of installation location

Provide chamfers on all edges of the cylinder and piston rod to prevent O-ring damage during installation, as shown in Table 2.5.3.

Table 2.5.3 Chamfer of O-ring installed area

unit mm

| O-ring cross section diameter | X (min.) | Z ¹⁾ | |
|-------------------------------|----------|-----------------|--------|
| | | At 15° | At 20° |
| — Up to 2.4 | 0.9 | 3.4 | 2.5 |
| Over 2.4 up to 3.5 | 1.1 | 4.1 | 3 |
| Over 3.5 up to 5.7 | 1.3 | 4.9 | 3.6 |
| Over 5.7 up to 8.4 | 1.5 | 5.6 | 4.1 |

Note 1) Dimension Z is shown when dimension X is minimum.

When O-ring is used on piston seal, do not provide a pressure hole on the area on which the O-ring slides.

If O-ring does pass on pressure hole when it is installed, chamfer around the hole edge and remove burrs (Fig. 2.5.2).

When the pressure hole is not chamfered:

When the pressure hole is chamfered:

Fig. 2.5.2 Chamfer of pressure-hole edges

(5) Material and surface finishing of fitting groove parts

Cylinder material for dynamic-sealing application should be steel. The most suitable rod material is hardened steel.

Soft materials such as aluminum, brass, bronze, Monel metal and soft stainless steel are not suitable as a sliding surface material because of inferior in abrasion resistance.

For static-sealing applications, materials should have sufficient strength to normal operation pressure and should also be resistant to pulsating pressure.

Surface finishing methods to minimize friction are honing, varnishing (roller varnishing), and polishing after hard nickel plating.

Hard-nickel plating is preferable for the application which requires heat resistance, abrasion resistance and low-friction.

Table 2.5.4 shows materials for fitting groove parts and their compatibility

Table 2.5.4 Groove materials and compatibility

| Metal | Corrosion resistance | Abrasion resistance | Contamination resistance | Metal protection | O-ring | |
|---------|--|---------------------|--------------------------|------------------|--------------------------------------|-----------------|

2.6 O-ring handling

(1) Storage

The following practices are advisable to keep O-ring quality for a long time.

- 1) Do not store where exposed to direct sunlight.
- 2) Store enclosed indoors where temperature is less than 30 °C and humidity is less than 65 %.
- 3) Keep O-rings away from heat or ozone sources.
- 4) O-rings should be sealed completely in packages when stored.
- 5) Do not hang or suspend O-rings on hooks, wires, or strings.

(2) Handling

- 1) Avoid reuse of used O-rings.
- 2) When installing an O-ring, apply sealing fluid (lubricant) to the O-ring and contact surface.
- 3) Install an O-ring in the groove without twisting it.
- 4) Take care when O-ring equipped machine should be cleaned with cleaning oil or gasoline and protect O-ring from cleaning oil because the rubber may be swelled.
- 5) If an O-ring passes along a threaded surface or sharp edges during installation, take care not to damage the O-ring by using the following protection cap on the thread area as shown in Fig. 2.6.1.

Fig. 2.6.1 O-ring installation jig

2.7 Typical O-ring failures, causes and countermeasures

When leakage is observed, investigate the causes and implement proper countermeasures.

To identify the causes, it is critical to observe the O-ring closely and evaluate the failure in all respects, such as cylinder, piston, and fluid to be sealed.

Table 2.7.1 O-ring failures, causes and countermeasures

Ⓓ : Dynamic sealing Ⓔ : Static sealing

| Phenomenon | Appearance | | Major causes | Countermeasures |
|---|---|--|---|--|
| | Condition | | | |
| Ⓓ Twist | Twisted and deformed | | <ul style="list-style-type: none"> Excessive speed Eccentric movements Poor surface finish on sliding face Twisted installation | <ul style="list-style-type: none"> Replace with V-packing Improve accuracy of equipment Improve sliding surface finish Install with care(Coat grease.) |
| Ⓓ Chipping | Partially chipped | | <ul style="list-style-type: none"> Chipped by the bore edge, threads, or sharp corner at installation | <ul style="list-style-type: none"> Round all sharp edges Use an installation jig |

Notes 1) The tolerance of bore diameter d_1 shows the specified values in JIS B 2401 for class 1-A, 1-B, 2 and 3 products. For class 4-C products, the tolerance is 1.5 times these values, and for class 4-D products, 1.2 times.
2) For a static sealing application on a flat surface, design the groove according to dimension d_s for use under external pressure, or according to dimension d_7 for use under internal pressure. An O-ring for use under external pressure can thus have its bore surface in close contact with the inner wall of the groove during use. Likewise an O-ring for use under internal pressure can thus have its circumferential surface in close contact with the outer wall of the groove.

3) The fitting code is corresponding to the d_4 and d_6 tolerances.
4) Eccentricity E means the difference between the maximum value and minimum value of dimension K . The eccentricity can also be defined as double the coaxiality measurement.

■ O-ring shape and dimensions (unit mm)

■ Fitting groove dimensions

For static sealing on cylindrical surface

For dynamic sealing

■ Fitting groove design (unit mm)

■ Backup rings

(For dynamic sealing and static sealing on cylindrical surface)

P 35.5~105

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

Notes 1) The tolerance of bore diameter d_1 shows the specified values in JIS B 2401 for class 1-A, 1-B, 2 and 3 products. For class 4-C products, the tolerance is 1.5 times these values, and for class 4-D products, 1.2 times.
2) For a static sealing application on a flat surface, design the groove according to dimension d_s for use under external pressure, or according to dimension d_7 for use under internal pressure. An O-ring for use under external pressure can thus have its bore surface in close contact with the inner wall of the groove during use. Likewise an O-ring for use under internal pressure can thus have its circumferential surface in close contact with the outer wall of the groove.

3) The fitting code is corresponding to the d_4 and d_6 tolerances.
4) Eccentricity E means the difference between the maximum value and minimum value of dimension K . The eccentricity can also be defined as double the coaxiality measurement.

Notes 1) The tolerance of bore diameter d_1 shows the specified values in JIS B 2401 for class 1-A, 1-B, 2 and 3 products. For class 4-C products, the tolerance is 1.5 times these values, and for class 4-D products, 1.2 times.
2) For a static sealing application on a flat surface, design the groove according to dimension d_s for use under external pressure, or according to dimension d_7 for use under internal pressure. An O-ring for use under external pressure can thus have its bore surface in close contact with the inner wall of the groove during use. Likewise an O-ring for use under internal pressure can thus have its circumferential surface in close contact with the outer wall of the groove.

3) The fitting code is corresponding to the d_4 and d_6 tolerances.
4) Eccentricity E means the difference between the maximum value and minimum value of dimension K . The eccentricity can also be defined as double the coaxiality measurement.

■ Fitting groove dimensions (unit mm)

| Cross section dia. d_2 | Corner radius r_1 |
|--------------------------|---------------------|
| 1.80 | 0.3 ± 0.1 |
| 2.65 | 0.3 ± 0.1 |
| 3.55 | 0.6 ± 0.2 |
| 5.30 | 0.6 ± 0.2 |
| 7.00 | 1.0 ± 0.2 |

1) Groove depth

Determine dimension h to obtain O-ring compression amount between 8 % and 30 %.

$$\text{Compression amount} = \frac{d_2 - h}{d_2} \times 100 (\%) = 8 \% \sim 30 \%$$

Determine the radial gap by the consideration that the double radial gap (gap in diameter) should be less than the value shown in Fig. 2.5.1.

Therefore: $K = h - \text{gap in radial}$
 d_2 : O-ring cross section diameter

2) Groove width (b)

Determine groove width by the consideration that O-ring should not occupy more than 90 % of the groove space.

$$\text{Occupancy percentage} = \frac{\pi \times (d_2/2)^2}{b \times h} \times 100 (\%) < 90 \%$$

Notes 1) For a static sealing application on a flat surface, design the groove according to dimension d_8 for use under external pressure, or according to dimension d_7 for use under internal pressure. An O-ring for use under external pressure can thus have its bore surface in close contact with the inner wall of the groove during use. Likewise an O-ring for use under internal pressure can thus have its circumferential surface in close contact with the outer wall of the groove.
2) Eccentricity E means the difference between the maximum value and minimum value of dimension K . The eccentricity can also be defined as double the coaxiality measurement.

Notes 1) For a static sealing application on a flat surface, design the groove according to dimension d_8 for use under external pressure, or according to dimension d_7 for use under internal pressure. An O-ring for use under external pressure can thus have its bore surface in close contact with the inner wall of the groove during use. Likewise an O-ring for use under internal pressure can thus have its circumferential surface in close contact with the outer wall of the groove.
2) Eccentricity E means the difference between the maximum value and minimum value of dimension K . The eccentricity can also be defined as double the coaxiality measurement.

Notes 1) For a static sealing application on a flat surface, design the groove according to dimension d_s for use under external pressure, or according to dimension d_7 for use under internal pressure. An O-ring for use under external pressure can thus have its bore surface in close contact with the inner wall of the groove during use. Likewise an O-ring for use under internal pressure can thus have its circumferential surface in close contact with the outer wall of the groove.
2) Eccentricity E means the difference between the maximum value and minimum value of dimension K . The eccentricity can also be defined as double the coaxiality measurement.

■ O-ring shape and dimensions (unit mm)

■ Fitting groove dimensions (unit mm)

- Groove depth**
 Determine dimension h to obtain O-ring compression amount between 8 % and 30 %.

$$\text{Compression amount} = \frac{d_2 - h}{d_2} \times 100 (\%) = 8 \% \sim 30 \%$$
 Determine the radial gap by the consideration that the double radial gap (gap in diameter) should be less than the value shown in Fig. 2.5.1.
 Therefore: $K = h - \text{gap in radial}$
 d_2 : O-ring cross section diameter
- Groove width (b)**
 Determine groove width by the consideration that O-ring should not occupy more than 90 % of the groove space.

$$\text{Occupancy percentage} = \frac{\pi \times (d_2/2)^2}{b \times h} \times 100 (\%) < 90 \%$$

■ O-ring shape and dimensions (unit mm)

■ Fitting groove dimensions (unit mm)

- Groove depth**
 Determine dimension h to obtain O-ring compression amount between 8 % and 30 %.

$$\text{Compression amount} = \frac{d_2 - h}{d_2} \times 100 (\%) = 8 \% \sim 30 \%$$
 Determine the radial gap by the consideration that the double radial gap (gap in diameter) should be less than the value shown in Fig. 2.5.1.
 Therefore: $K = h - \text{gap in radial}$
 d_2 : O-ring cross section diameter
- Groove width (b)**
 Determine groove width by the consideration that O-ring should not occupy more than 90 % of the groove space.

$$\text{Occupancy percentage} = \frac{\pi \times (d_2/2)^2}{b \times h} \times 100 (\%) < 90 \%$$

- Notes
- 1) The cut angle for P3 to P10 is 35°~40°.
 - 2) The dimensions shown in the "Bias-cut and Endless ring" column are the dimensions of endless rings. Bias-cut rings are produced by cutting endless rings.
 - 3) In the case of bias-cut and endless ring, the deviation of ring thickness W (within one piece) shall be 0.05 mm max.
 - 4) The clearance Z is shown when the backup ring is installed on a shaft toleranced to 0 mm / - 0.05 mm.

4.1 Rubber-material varieties and properties

This table compares the properties of all available rubber materials, including those that are not suitable for oil seals and O-rings.

⊙ : Resistant to the substance.
 ○ : Resistant to the substance except under extreme conditions.
 △ : Not resistant to the substance except under specific favorable conditions.
 × : Not resistant to the substance.

| Kind of rubber (ASTM code) | | Nitrile rubber (NBR) | Hydrogenated nitrile rubber (HNBR) | Acrylic rubber (ACM and ANM) | Silicone rubber (VMQ) | Fluorocarbon rubber (FKM) | Chloroprene rubber (CR) | Ethylene-propylene rubber (EPM and EPDM) | Styrene-butadiene rubber (SBR) | Urethane rubber (U) | Natural rubber and isoprene rubber (NR and IR) | Butadiene rubber (BR) | Butyl rubber (IIR) | Chlorosulfonated polyethylene rubber (CSM) |

| Typical properties and major applications | | The most common oil-resistant rubber material. Good resistance to abrasion. Widely used for oil seals and O-rings. | Excellent heat resistance and mechanical strength, in addition to having properties of nitrile rubber. An optimal material for oil seals for high-temperature or hydraulic applications. | Compared with nitrile rubber, superior in aging resistance. Suitable for sealing hydraulic fluids. Commonly used in automotive applications such as transmission, crankshaft, and valve stem. | Siloxane-based, excellent heat resistance and low-temperature resistance. Suitable for extreme-temperature environments and food processing applications. | Superior to other rubber materials in performance in extreme environments. Optimal for use in proximity to engines. | Well-balanced in resistance to weather, oil and heat. Commonly used to isolate vibration and to coat wires. Some cases used for oil seals and O-rings. | Excellent weatherproof and water-proof. It is used for clad automobiles and wires. | Compared with natural rubber, superior in resistance to abrasion and aging. Used as the material of tires and belts. | Superior mechanical strength and oil resistance, however relatively low heat resistance and water-proofness. Used in applications where heat resistance is not essential. | Excellent resilience and superior abrasion resistance. Oil resistance is relatively low. Used for tires and shoes. | Excellent in resilience and mechanical strength. But inferior in resistance to oil and to pressure fluctuations. Used for produce tires and sport goods. | Low gas permeability and inferior in resilience. Commonly used for tubes and vibration isolators. | Superior aging resistance and chemical resistance. Used for hoses and cladding. |

Note 1) Hardness measured by durometer.

| Quantity of electricity | { 1 C = 1 A · s } | | | |
| Tension | V [volt(s)] | | | |
| Electric potential | { 1 V = 1 W/A } | | | |
| Capacitance | F [farad(s)] { 1 F = 1 C/V } | | | |
| Magnetic field strength | A/m | Oe [oersted(s)] | 1 Oe = $\frac{10^3}{4\pi}$ A/m | 1 A/m = 4π × 10 ⁻³ Oe |
| Magnetic flux density | T [tesla(s)] { 1 T = 1 N/(A · m) = 1 Wb/m ² = 1 V · s/m ² } | Gs [gauss(es)] γ [gamma(s)] | 1 Gs = 10 ⁻⁴ T 1 γ = 10 ⁻⁹ T | 1 T = 10 ⁴ Gs 1 T = 10 ⁹ γ |
| Magnetic flux | Wb [weber(s)] { 1 Wb = 1 V · s } | Mx [maxwell(s)] | 1 Mx = 10 ⁻⁸ Wb | 1 Wb = 10 ⁸ Mx |
| Self inductance | H [henry (ries)] { 1 H = 1 Wb/A } | | | |
| Resistance (to direct current) | Ω [ohm(s)] { 1 Ω = 1 V/A } | | | |
| Conductance (to direct current) | S [siemens] { 1 S = 1 A/V } | | | |
| Active power | W { 1 W = 1 J/s = 1 A · V } | | | |

4.3 Shaft tolerance

Example

The center columns of numbers is the temperature in either degrees Centigrade (°C) or Fahrenheit (°F) whichever is desired to convert into the other. If degrees Fahrenheit is given, read degrees Centigrade to the left. If degrees Centigrade is given, read degrees Fahrenheit to the right.

$$C = \frac{5}{9}(F - 32)$$

$$F = \frac{9}{5}C + 32$$

| | Surface finishing method | | | | | Lubrication method | | | |
| Surface roughness | | | | Oil bath / Circulation / Splash / Drip / Other () | | | | | |

Mounting procedure

- Housing shoulder diameter F :
- Housing bore depth B_1 :
- Housing bore radius R :
- Seal mounting direction into housing: X/Y
- Seal mounting direction onto shaft: A/B
- Shaft rotational direction: Right/Left/Bi-direction
 (Right: Clockwise when viewed from oil seal back face
 Left: Counterclockwise when viewed from oil seal back face)

☆ Please specify as many items as possible to enable correct product design and selection.

Request Form for Oil Seal Design and Production (2)

| | | | | | | |
|--|------------|--------|------------------------|-----------------|---------------------|---------------------|
| Shaft diameter | Changeable | Yes/No | To ____ mm (max. min.) | Oil seal type | Your requested type | Yes () / No |
| Housing bore diameter | Changeable | Yes/No | To ____ mm (max. min.) | Rubber material | Your requested type | Yes () / No |
| Width | Changeable | Yes/No | To ____ mm (max. min.) | Other | | |
| Requested oil seal life | | | | | | |
| <p>Mounting location details (Attach drawing of the oil seal location, if possible).</p> | | | | | | |
| <p>Requests/Questions</p> | | | | | | |

☆ Please specify as many items as possible to enable correct product design and selection.
